76 A B S T R A C T

The aim of the present study was to assess the cultivable microbiota of "mothers" of Vino cotto 77 collected from production of different years 1890, 1895, 1920, 1975, 2008. A total of 73 yeasts and 78 81 bacteria were isolated. Starmerella lactis-condensi, Starmerella bacillaris, Hanseniaspora 79 uvarum, Saccharomyces cerevisiae, Hanseniaspora guillermondi and Metschnikowia pulcherrima 80 were identified. Bacteria isolates belonged to lactic acid bacteria (Lactiplantibacillus plantarum and 81 Pediococcus pentosaceus) and acetic acid bacteria (Gluconobacter oxydans). Remarkable 82 biodiversity was observed for Starm. bacillaris, as well as L. plantarum and G. oxydans. Organic 83 acids and volatile compounds were also determined. Malic and succinic acids were the main ones 84 with values ranging from 8.49 g/L to 11.76 g/L and from 4.15 g/L to 7.73 g/L respectively, while 85 citric acid was present at low concentrations (<0.2 g/L) in all samples. Esters and higher alcohols 86 87 were the main volatile compounds detected followed by alkanes. This study permits to better understand the microbial communities associated to this product and could be considered a starting 88 89 point for the definition of tailored starter cultures to improve the quality of Vino cotto preserving its typical traits. 90

110 **1. Introduction**

Vino cotto (cooked wine) is a typical sweet wine produced in Abruzzo and Marche regions. It was 111 inserted in the national list of traditional food products for Marche and Abruzzo regions in 2000 and 112 2003, respectively, and can be marketed as traditional agrifood product (Repubblica Italiana 2000; 113 2003). It is produced according to traditional procedures using different grape cultivars including 114 Trebbiano, Passerina, Montonico, Moscato, Montepulciano and Sangiovese. The must is heated and 115 concentrated to 30-70% in copper boilers. To start the alcoholic fermentation fresh must can be 116 117 added so the indigenous yeasts can drive the fermentation process which proceeds very slowly for more than a month at room temperature because of the high concentration of sugar and other 118 naturally occurring substances such as acids, polyphenols, metal ions, and the formation of Maillard 119 reaction products (Piva et al., 2008). Once the fermentation ends Vino cotto is transferred in 120 121 wooden barrels. In the bottom of barrels, the must/wine which settles over the years and gives the characteristic aroma and flavour of Vino cotto is present (Tofalo et al., 2009). This mixture is called 122 by local producers "mother" of Vino cotto. Therefore, each barrel is a unique niche where a peculiar 123 microbiota can develop. Very few studies have been carried out to study the microorganisms hosted 124 125 by "mother" of Vino cotto and Vino cotto wine. It represents a very stressing environment since microorganisms are exposed to osmotic stress which cause the loss of intracellular water and the 126 collapse of cytoskeleton (Hohmann, 2002). In general, osmotolerant yeasts could grow facing the 127 128 stressing conditions since they are able to retain the ability to synthesize glycerol as a compatible solute or osmoregulator, and some yeasts even have active glycerol uptake pumps (Hohmann, 129 2002). In a previous study Tofalo et al. (2009) isolated, identified and characterized the 130 predominant indigenous yeast species during Vino cotto production. Only four species were 131 identified: Saccharomyces cerevisiae, Candida apicola, Starmerella bacillaris (syn. Candida 132 *zemplinina*) and *Zygosaccharomyces bailii*. All the species showed osmotolerant traits being able to 133 develop in presence of high concentration of glucose in a strain dependent way. 134

No data are available concerning bacteria. However, some bacterial group can also develop. In
particular, lactic acid bacteria (LAB) and acetic acid bacteria (AAB).

LAB are able to face different stress conditions since they Harbour specific genes and they have evolved adaptive networks such as the so called Global Regulatory Systems. It controls the simultaneous expression of a large number of genes in response to a variety of environmental stress factors (Spano & Massa, 2006). Moreover, they were isolated in "Shanxi aged vinegar", a traditional Chinese vinegar (Wu, Ma, Zhang, & Chen, 2012).

AAB are found on stressing substrates containing sugars and/or alcohol, such as fruit juice, wine,
cider, beer, and vinegar (Mas, Torija, García-Parrilla, & Troncoso, 2014; Calabrò, Fazzino, Sidari,

& Zema, 2020) and they are able to survive in Traditional Balsamic Vinegar, another Italian
traditional product made with cooked grape must (Solieri, Landi, De Vero, & Giudici, 2006).

In light of the above, the aim of the present work was to determine the cultivable microorganisms associated with "mothers" of Vino cotto collected from barrels of different years (1890, 1920, 1926, 1980, 2008). Specifically, AAB, LAB and yeasts were enumerated and isolated. Isolates identification was performed as well as their genotypic grouping in order to verify if a core microbiota was conserved over years. Moreover, samples were characterized for organic acids and polyphenols content and volatile profile.

152

153 **2. 2. Materials and methods**

154 2.1. Samples origin

Five barrels of different years (1890, 1895, 1920, 1975, 2008) containing "mothers" of Vino cotto were analyzed. Samples were named as follow: V1890, V1895, V1920, V1975, V2008. Samples were obtained from a local winery of Abruzzo region, collected in sterile tubes and transported to the microbiological laboratory of the Faculty of BioScience and Technology for Food, Agriculture and Environment (University of Teramo) and analyzed.

160 *2.2. Microbial counts*

161 Samples were diluted in physiological solution (NaCl 0.85% w/v) and serially diluted. Cell suspensions were spread-plated and incubated as follows: yeasts on YPD agar (Yeast Extract 10 162 163 g/L, Peptone 20 g/L, Dextrose 20 g/L, Agar 18 g/L) and on Wallerstein Laboratory Nutrient Agar (WLN) (Oxoid, Milan, Italy) at 28 °C for 48 h; LAB on DeMan-Rogosa-Sharp Agar (MRS) 164 (Oxoid) with 100 ppm cycloheximide at 30 °C for 48 h in microaerophilic conditions; AAB on 165 166 GYC medium (Glucose 100 g/L, Yeast Extract 10 g/L, Calcium Carbonate 20 g/L, Agar 1.5 g/L) – 167 a common medium useful to isolate AAB from sources rich in sugar - at 30 °C for 48 h in aerobic conditions (Gullo, Caggia, De Vero, & Giudici, 2006). Cell counts were performed in duplicate. 168

The random colony selection from the highest dilution plates allowed us to collect the most frequent species present in each sample, as reported by Tofalo et al. (2009), and Solieri et al. (2006). Isolates were purified and stored in liquid cultures with glycerol (20% v/v) (Sigma Aldrich, Milan, Italy) at -80 °C. Strains belong to the Culture Collection of the Faculty of BioScience and Technology for Food, Agriculture and Environment (University of Teramo).

174

175 *2.3. Yeasts identification and typing*

Yeast cells were grown aerobically in YPD at 28 °C. DNA was extracted according to Aa,
Townsend, Adams, Nielsen, and Taylor (2006). The 5.8S internal transcribed spacer (ITS) rRNA

region was amplified in a Bio-Rad thermocycler (MyCycler, Bio-Rad Laboratories, Milan, Italy) 178 TCCGTAGGTGAACCTGCGG 3' (5' 179 using primers ITS1 (5') and ITS4 TCCTCCGCTTATTGATATGC 3'). The PCR product was digested with the restriction enzymes 180 CfoI, HaeIII and HinfI as previously described (Esteve-Zarzoso, Belloch, Uruburu, & Querol, 1999; 181 Tofalo et al., 2009). In order to have a confirmation of the species, sequencing of the D1/D2 182 of 26S rRNA 183 domains gene was conducted using primers NL1 (5) GCATATCAATAAGCGGAGGAAAAG 3') and NL4 (5' GGTCCGTGTTTCAAGACGG 3') 184 (Kurtzman & Robnett, 1998). The PCR product was purified by ExoSAP-IT (Thermofisher, Milan, 185 Italy) according to manufacturer's instructions and delivered to BMR Genomics (Padua University, 186 Padua, Italy) for sequencing. The obtained sequenze were compared to those available in the 187 GenBank database (http://www.ncbi.nml.nih.gov/BLAST) and those of the Ribosomal Database 188 Project (http://rdp.cme.msu.edu/index.jsp) to determine the closest known relative species on the 189 190 basis of 26S rRNA gene homology (Altschul et al., 1997).

Strains were typed by RAPD-PCR with primer M13 (5' GAGGGTGGCGGTTCT 3') as previously described (Tofalo et al., 2009). Fingerprinting II InformatixTM software program (Bio-Rad) was employed for conversion and normalization of the RAPD-PCR patterns. Similarities among profiles were calculated by clustering the Pearson's r correlation matrix using the Unweighted Pair-Group Method with Average (UPGMA) algorithm.

196

197 2.4. Bacteria identification and typing

DNA was extracted using InstaGene Matrix (Bio-Rad) according to manufacturer's instructions. Bacterial isolates were identified by 16S rRNA gene sequencing. PCR reactions were performed as described by Bringel et al. (2005) using Lac16S-for (5' AATGAGAGTTTGATCCTGGCT 3') and Lac16S-rev (5' GAGGTGATCCAGCCGCAGGTT 3') primer set. PCR products were purified and sent to BMR Genomics for sequence analysis. *Lactiplantibacillus plantarum, L. pentosus*, and *L. paraplantarum* were differentiated by multiplex PCR according to Torriani, Felis, & Dellalglio (2001). Molecular typing was performed by M13 RAPD-PCR as previously described.

205

206 2.5. Organic acids analysis

Organic acids of "mothers" of Vino cotto samples were detected by HPLC according to Tašev, Stefova, and Ivanova (2016) and Piva et al. (2008). All chemicals were of analytical reagent grade and supplied by Sigma Aldrich. To separate organic acids from other components, solid phase extraction (SPE) was performed. Samples were diluted 1:10 and filtered, then extracted with SPE using Supelclean LC-18 SPE 500 mg cartridges (Sigma Aldrich). The cartridges were conditioned

with 2 mL methanol and 2 mL water. Then, 500 µL of samples were loaded on the cartridges. 212 Elution was performed with two portions (500 µL each) of buffered water at pH 2.1. Finally, 10 µL 213 of the eluate was injected into the HPLC system for analysis. Organic acids (citric acid, tartaric 214 acid, malic acid, succinic acid, lactic acid and acetic acid – Sigma Aldrich) were used to create the 215 standard curve. The detector was an HPLC 200 series (Perkin Elmer, Monza, Italy) connected to a 216 UV VIS detector at 210 nm. ROA Organic Acid H + column (Phenomenex, Bologna, Italy) was 217 used. All determinations were performed isocratically with a flow rate of 0.7 mL/min at 65 °C using 218 H₂SO₄ solution 0.009 N as mobile phase. Analyses were performed in triplicate. 219

220

221 2.6. Volatile compounds

Volatile compounds were analyzed using gas chromatography/mass spectrometry (GC-MS) as 222 described by Tofalo et al. (2016). Analyses were performed using a Clarus SQ8S 223 chromatography/mass (GC-MS) spectrometry (Perkin Elmer, Boston, MA). The column used was a 224 capillary GC column (30 m \times 0.25 mm i.d. 0.25 μ m film thickness) coated with polyethyleneglycol 225 226 (film thickness 1.2 µm), as stationary phase. A carboxen–polydimethylsiloxane-coated fiber (85 µm) was used (Sigma-Aldrich, St. Louis, MO, USA). Equilibration and adsorption steps were 227 228 performed stirring the samples for 30 min at 40 °C. The fiber was placed in the injector (T = 250°C) for 15 min and the following program was applied: 50 °C for 2 min; first ramp, 1 °C min to 65 229 °C; second ramp, 10 °C min to 150 °C (10 min hold); third ramp 10 °C min to 200 °C (1 min hold). 230 Volatile compounds were identified comparing mass spectra of compounds with those contained in 231 232 the available database (NIST version 2005). All determinations were performed in triplicate.

233

234 2.7. Statistical analysis

Organic acids and volatile compounds results were expressed as mean value \pm standard deviation. The Friedman's test was used and p < 0.01 was used as criterion for statistical significance.

- Principal component analysis (PCA) based on the main volatile compounds, organic acids and
 samples was performed using the software XLStat 2014 (Addinsoft, New York, NY, United States).
- 239

240 **3. Results and discussion**

241 *3.1. Microbial counts*

This study evaluated viable microbial communities hosted by "mothers" of Vino cotto of different years. Yeasts were detected in all samples with values ranging from 2.7 Log CFU/mL (V1890) to 3.5 Log CFU/mL (V2008) (Fig. 1). These results are similar to other studies on high content sugary foods (i.e. honey and manna), which are recognized as a stressful environment, and allow the

growth of osmotolerant microorganisms (Snowdon & Cliver, 1996; Fe'as, Pires, Iglesias, & 246 Estevinho, 2010; Sinacori et al., 2014; Guarcello et al., 2019). Yeast counts increased over time 247 showing the highest values in samples obtained from the newest barrels. LAB showed a similar 248 trend. They were present only in "mothers" of Vino cotto collected from the most recent barrels 249 ranging from 2 Log CFU/mL (V1980) to 6.12 Log CFU/mL (V2008). In the other samples they 250 showed values of microbial count less than the limit of detection. An opposite tendency was 251 observed for AAB. In fact, they were detected in the oldest 3 samples with values from 4 Log CFU/ 252 mL (V1890) to 2 Log CFU/mL (V1920), while were absent in "mothers" of Vino cotto obtained 253 254 from the newest barrels (V1975, V2008) (Fig. 1).

Therefore, samples from barrels of V1890, V1895 and V1920 were characterized by the presence of yeasts and AAB, while those of V1975 and V2008 by yeasts and LAB. The different occurrence of microbial groups could influence fermentation kinetics resulting in different organoleptic characteristics which make this product unique and with traits which are different from year to year. Probably, the occurrence of AAB is influenced by oxygen availability, which is higher in the oldest barrels.

No data are available concerning the microbial groups characterizing "mothers" of Vino cotto. Tofalo et al. (2009) studied the yeast population occurring during the different steps of Vino cotto production. At the beginning of fermentation, after the addition of fresh must, yeast counts were 6.3 Log CFU/mL, and a maximum number of 8.2 Log CFU/mL was reached during fermentation, while at the late stages of the process the viable cells decreased to 5.1 Log CFU/mL.

However, the same yeast species were detected by other authors in similar products obtained by cooked must, such as balsamic vinegars (TBV) (Solieri et al., 2006; Gullo et al., 2006). The presence of AAB is associated to their ability to resist to acid environment (pH 2.5 - 3.5).

Moreover, they are able to grow at elevated sugar concentration characterizing this product (Gullo et al., 2006). LAB are able to tolerate different stressing conditions thanks to their genetic, and can promote a soft taste by moderating the irritating sour smell (Chen, Li, Qu, & Chen, 2009).

273 274

275 *3.2. Yeast identification and typing*

Colonies were selected on WLN and YPD media according to colony shape, colour and surface
features. To attribute the species, PCR-RFLP and sequencing of D1/D2 domine of 26S rRNA gene
were performer and compared with those available in the EMBL nucleotide sequence database.
(Table S1). All the sequences obtained displayed similarità values ranging from 99 to 100%.

As regards yeasts, a total of 73 colonies were isolated. Starmerella lactis-condensi (30), Starm. 280 bacillaris (16), Hanseniaspora uvarum (13), Saccharomyces cerevisiae (7), Hanseniaspora 281 guillermondi (5) and Metschnikowia pulcherrima (2) species were identified (Fig. 2). Starm.lactis-282 condensi, which was present in all samples, is a relative of Starmerella stellata and Starm. bacillaris 283 (syn. Candida zemplinina). The yeasts belonging to these species are osmotolerant and able to grow 284 also on 50% w/w glucose, a typical characteristic of Starmerella clade (Kurtzman, Fell & Boekhout, 285 2011). Osmotolerant yeasts are characterized by their ability to survive high osmotic pressure in the 286 287 environment, caused by the presence of sugars or salts. The adaptation to a low water activity (aw) environment is a species and strain specific trait and it is generally based on modification in plasma 288 289 membrane composition, activity of various ion transporters or redox metabolism (Hohmann, 2002; Thomè, 2007). Starm lactis-condensi is nutritionally specialized and has been previously found in 290 291 sugar syrups, manna and TBV. Probably, it could be brought on fruits by insects, like bees and wasps, which could be a vector for their spreading (Lievens et al., 2015; Solieri & Giudici, 2008; 292 Guarcello et al., 2019). The occurrence of Starm. bacillaris (syn. C. zemplinina) in "mothers" of 293 Vino cotto is not surprisingly, since Tofalo et al. (2009) found this species throughout all the 294 295 fermentation process of Vino cotto. Its presence is related to its osmotolerance, in fact it grows 296 like or better than S. cerevisiae in media with high sugar contents (Tofalo et al., 2009). Several

ecology studies reported the occurrence of Starm. bacillaris in both white and red wines from 297 different origin as well as in botrytized grape (Masneuf-Pomarede et al., 2015). When it is used in 298 mixed fermentation with S. cerevisiae, it produces wine with reduced ethanol content and an 299 300 increased concentration of glycerol (Englezos et al., 2015). This trait is interesting since the global warming and the evolution of viticulture practices led to grape must with increased sugar content 301 302 and thus increased potential ethanol content (Englezos et al., 2015). Starm. bacillaris presents other interesting features such as the fructophilic character (Magyar & Tóth, 2011; Tofalo et al., 2012; 303 Englezos et al., 2015), and the antifungal activity against Botrytis cinerea (Lemos et al., 2016). 304

The ascomycetous yeast *Metschnikowia* dominates most nectar microbial communities and it is often transferred from insects or birds, from flower to flower or from flower to fruit (Lievens et al., 2015). Sugar composition and concentration is crucial for its development, but this species is able to exploit a diversity of resources efficiently, which help it to survive in nectars (Herrera, Pozo, &
Bazaga, 2012). In high sugary foods, such as high sugar grape musts, wines produced with dried or

botrytized grapes, honey or manna, non-*Saccharomyces* yeasts are usually dominant (Sinacori et al.,
2014; De Filippis et al., 2019). *S. cerevisiae* is not recognized as osmotolerant yeast, but its survival
is a strain specific characteristic, and it has also been previously isolated in Vino cotto and TBV
(Tofalo et al., 2009; Solieri & Giudici, 2009). In this study, a total of 7 isolates of *S. cerevisiae* have
been found in the "mothers" of Vino cotto of the following years V1890, V1920, V2008.

H. uvarum was isolated from V1920, V1975 and V2008 samples. It is usually predominant in the early stages of wine fermentation or fruit juices, and it can occur also during middle and late phases (Kurtzman et al., 2011). Some strains previously showed fructophilic character and relevant glycerol production (De Benedictis, Bleve, Grieco, Tristezza, & Tufariello, 2011). It has been found in sweet wines such as passito wines (De Filippis et al., 2019) or pulque, an alcoholic beverage from agave (Steinkraus, 2002).

Repeatability of RAPD-PCR fingerprints was determined by triplicate loading of independent 321 322 triplicate reaction mixtures prepared with the same strain and a limited variability in the number and length of the resulting bands. The reproducibility of PCR assays and running conditions was higher 323 324 than 90%. Banding patterns with a level of similarità higher than 90% was considered as a biotype. UPGMA dendrogram is shown in Fig. 3. RAPD-PCR resulted in a coherent classification at the 325 species level. A single biotype was found for H. uvarum, H. guillermonndi, M. pulcherrima, Starm. 326 lactis-condensi and S. cerevisiae strains, while two biotypes for Starm bacillaris strains. These 327 results suggested strain adaptability to this niche along the year of production sampled. This low 328 RAPD-PCR diversity can be explained by the supposed prevalence of a small number of dominant 329 species or "core" strains, selected by the stressful conditions imposed by this peculiar environment, 330 similarly to what happens in other ecological niches (Biolcati, Andrighetto, Bottero, & Dalmasso, 331 2020). 332

(UPGMA) dendrogram derived from comparison of the RAPD-PCR patterns of the yeast isolates obtained
with primer M13.

343

344 *3.3. Bacterial identification and typing*

A total of 81 colonies were isolated and only 3 species were identified (Table S2). In samples V1890, V1895

and V1920 only *Gluconobacter oxydans* (36) was found. In samples V1975 and V2008 were isolated LAB

347 belonging to *Pediococcus pentosaceus* (12) and *L. plantarum* (33) species (Fig. 4). The confirmation of *L.*

348 *plantarum* species was conducted after amplification of recA gene which resulted in the presence of the band 349 at 318 bp for all the strains.

Generally, *G. oxydans* can be found in sugary niches such as flowers and fruits (De Muynck et al., 2007) and can be isolated from honey, cider, beer, wine and vinegar. The presence of *G. oxydans* in the "mothers" of Vino cotto is probably related to its metabolic traits: they can obtain energy from sugars efficiently via pentose phosphate pathway and glucose oxidation lead to the production of gluconic acid and can improve the flavour of the final product (Macauley, McNeil, & Harvey, 2001; De Muynck et al., 2007).

Lactiplantibacillus plantarum and *P. pentosaceus* isolates were found in the two most recent samples, V1975
 and V2008. LAB are generally highly demanding regarding nutrients, and sugar-rich environments can

inhibit their growth. Some fructophilic LAB have been found: they are able to develop in highly sugary

niches such as flowers, nectar and fruits, in the digestive tracts of pollinators, or in fermented foods derived
from fruits (Endo & Okada, 2008; Endo, Futagawa, & Dicks, 2009). Recently, some evidence about the

360 frucophilic attitude of a *L. plantarum* strain isolated from honeydew have been described (Gustaw, Michalak,

Polak-Berecka, & Wa´sko, 2018). It is likely that the strains found in our samples derived from the grapes
and were able to adapt themselves to the osmophilic environment they found, being able to survive.

P. pentosaceus is generally isolated in wine environment (must, alcoholic/malolactic fermentation, aging and conservation). It can grow in wines that are considered microbiologically stable, and its presence does not

always lead to spoilage, but can be useful for the malolactic fermentation. New findings have suggested
potential uses for *Pediococcus* spp. in winemaking but have also underlined the necessity to further study the
factors that influence its growth and spoilage potential (for a review see Wade, Strickland, Osborne, &
Edwards, 2019).

All bacteria were processed by RAPD-PCR analysis to differenziate them at strain level. A single biotype was obtained for *P. pentosaceus* strains (data not shown). On the contrary, 6 biotypes for *G. oxydans* were

was obtained for 1. periosaccus shains (data not shown). On the contary, o biotypes for 0. oxyaans were

detected. A relationship with sample origin was found (Fig. 5). V1890 sample showed 3 different profiles,
V1895 sample only one, while V1920 sample 2 biotypes. Ten biotypes were observed for *L. plantarum* and 6

- of them contained only a strain. Also, in this case strains clistere on the basis of their origin. In particular, for
 V1975 sample 5 biotypes were found, each of them with a single strain. For V2008 samples 5 clusters were
- identified and only one contained a strain (Fig. 6). This association of strains with their origin could be

explained by the existence of metabolic interdependencies between strains. It is possible that, specific strains
may have been selected and be prevalent with respect to the remaining microbial community.

with primer M13.

395

396 *3.4. Organic acids content*

397 Organic acids are produced through hydrolysis, biochemical metabolism and microbial actions during the fermentation process. Citric, tartaric, malic, succinic, lactic and acetic acids were detected in all samples 398 (Table 1). Malic and succinic acids were the main ones with values ranging from 8.49 g/L (V1975) to 11.76 399 g/L (V2008) and from 4.15 g/L (V1895) to 7.73 g/L (V2008), respectively. Citric acid was present at low 400 concentrations around 0.3 g/L in all samples, while tartaric, and acetic acids had values of about 2 g/L. 401 Lactic acid was detected only in small amounts. Organic acids have different origins, mainly grapes and 402 microbial metabolism. The presence of succinic acid is related to yeast metabolism and the high 403 concentration detected is in agreement with cell counts. Acetic acid and lactic acid are mainly produced 404 405 during alcohol and malolactic fermentations, and small amounts are also produced during thermal treatment 406 of must due to sugar degradation (Xia, Zhang, Duan, Zhang, & Wang, 2020). Malic, citric, and tartaric acids 407 mainly derive from grapes (Xia et al., 2020). They could all react with sugars, through a condensation 408 reaction, follone by CO₂ production, to give brown compounds (Lewis & Quackenbush, 1949). The same organic acids were detected also in Vino cotto samples by other authors with similar amounts (Piva et al., 409 410 2008; Di Mattia, Sacchetti, Seghetti, Piva, & Mastrocola, 2007) as well as in products obtained in a similar way such as vinegars. Similar amounts of malic, acetic, and citric acids were detected in botrytized wines 411 which are characterized by high sugar concentration (Kiss & Sass-Kiss, 2005). 412

413

414 *3.5. Determination of volatile profile*

The volatile metabolites are shown in Table 2. Aroma compounds belonged to seven different families:
esters, higher alcohols, aldehydes, alkanes, and acetals. Esters and higher alcohols were the main compounds
detected.

Esters showed total amounts ranging from 32.80 mg/L (V1895) to 96.17 mg/L (V1920). Ethyl esters of fatty acids were the most represented group. Their concentration depends on several factors including yeast species, fermentation temperature, aeration degree, and sugar content (Schreirer, 1980) and have very pleasant fruits, honey, and sweet scents which contribute to the aromatic finesse of wines (Ugliano &

422 Henschke, 2009). The main esters were butanedioic acid, diethyl ester (diethyl succinate) and ethyl acetate

423 with values varying from 4.63 mg/L (V1980) to 35.64 mg/L (V1920) and from 8.69 mg/L (V2008) to 13.78

mg/L (V1920), respectively. Butanedioic acid, diethyl ester is formed through the esterification of succinic
 acid and is associated to fruity melon and cooked apple notes. This compound occurs naturally in apples,

grapes, and cocoa and its odor threshold has been set at 1.2 mg/L (Peinado, Moreno, Bueno, Moreno, &
Mauricio, 2004). Its concentration increases during wine storage and aging (Cort'es-Di'eguez, Rodriguez-

428 Solana, Domínguez, & Díaz, 2015). Butanedioic acid, diethyl ester was also observed to increase in sweet

429 wines such as Sherry type wines (Moreno-García, Raposo, & Moreno, 2013) and natural sweet wines

430 (Issa-Issa et al., 2019). Ethyl acetate is formed by the action of yeasts during fermentation, and by the action

431 of AAB during ageing (Nogueira & Nascimento, 1999). Ethyl acetate is perceived as the odour of nail

polish remover when occurs above the sensory threshold (12 mg/L); at low amounts it confers fruity aromaproperties and adds complexity to wine.

Higher alcohols represent the other important group of volatiles identified in wine. The group is composed of 434 435 aliphatic and aromatic alcohols, most of which are products of yeast fermentation (Kotseridis & Baumes, 2000). Their concentrations ranged from 17.96 mg/L (V1890) to 49.47 mg/L (V1920) and the main 436 compounds detected were 1-butanol, 3-methyl and phenylethyl alcohol with values varying from 7.77 mg/L 437 438 (V1890) to 27.63 mg/L (V1920) and from 4.49 mg/L (V2008) to 12.11 mg/L (V1920), respectively. These 439 higher alcohols are positively related to the vegetal/pepper note of aged red wines and negatively related to 440 the intensity of the toasted and woody-old attributes (Aznar, L'opez, Cacho, & Ferreira, 2003). Recently 441 have been also proved the sensory importance of the pair 1-butanol, 3-methyl and isoamyl alcohol on wine 442 aroma perception and that the effects of the alcohols are extremely dependent on the aromatic context. In 443 poor aromatic contexts, lacking of specific aroma nuances other than those of the wine aroma base, the sensory effects are negligible confirming the aroma buffering effects of such wine aroma base. Only in 444 445 contexts in which aroma notes are clearly perceived, the effects become clearly noticeable (De-la-Fuente-446 Blanco, S'aenz-Navajas, & Ferreira, 2016).

447 Furfural and its derivatives were the main aldehydes detected. Their occurrence in "mothers" of Vino cotto is

448 probably related to the production process. In fact, they are considered as some of the main products of the 449 browning process (and markers of a heat treatment); and thus, they can play a role in delivering a dried and 450 cooked fruit flavor (Loizzo et al., 2013).

451 Among acetals 1,3-dioxolane, 2,4,5-trimethyl was the main compound detected and its occurrence has been

452 already described in "Zaoheibao" wine (Duan, Liu, Lv, Wu, & Wang, 2020).

453 Alkanes were well represented too, probably due to the coking process of the must. 3,3' -bi-p-menthane was

454 the most abundant with values ranging from 15.78 mg/L (V1980) to 29.42 mg/L (V1890). It is associated to

fennel and peppermint odor (Shigeto, Wada, & Kumazawa, 2020), and thus, could contribute to the balsamic

456 notes of Vino cotto.

3.6. Principal component analysis (PCA)

494 PCA allowed 73.41% of the total variance to be explained by the first two principal components (Fig. 7).
495 Based on the distribution of samples 3 groups can be identified. V1920 sample appeared far from the others
496 for its composition in terms of citric, succinic and acetic acids, esters, aldehydes, acetals, and higher
497 alcohols. V2008 and V1975 samples clustered together for LAB and yeast counts. V1890 and V1895
498 belonged to the 3rd group and were differentiated from the others for lactic acid, AAB, organic acids, and
499 alkanes. Obtained data suggested that the aging period exerts a strong effect in the definition of "mothers" of

500 Vino cotto traits indicating that it should be possible to modulate the characteristics of Vino cotto using 501 "mothers" of different years.

- 502
- 503

505 Fig. 7. PCA analysis encompassing organic acids, volatile compounds and cell counts.

506

507 4. Conclusions

"Mother" of Vino cotto is a highly selective environment. Isolated strains – especially Starm. bacillaris, L. 508 plantarum and G. oxydans - showed genetic diversity. Therefore, the source of a strain/species is a key 509 510 factor that affects the final genetic diversity of the individual population and different origins can favour or 511 disfavour certain species in terms of their strain genetic diversity development. The strict relation between 512 bacteria and origin suggests that they probably play a major role in the definition of final product characteristics. Knowing the resident population present in the barrels can improve the knowledge of this 513 traditional product and could represent a prerequisite for the selection of strains ad hoc for Vino cotto. 514 Further studies on physiological and genetic characteristics of microbiota could contribute to a better 515 understanding of microbial ecology and to improve the quality of this old traditional product maintaining a 516

- 517 strong link with the territory.
- 518

519 Declaration of Competing Interest

520 The authors declare that they have no known competing financial interests or personal relationships that 521 could have appeared to influence the work reported in this paper.

522

523 Acknowledgment

This research was funded by University of Teramo FARDIB-2019 and by Progetto DM61315 "Sviluppo
della qualit`a delle produzioni vitivinicole abruzzesi". The authors are grateful to "Azienda Agricola Cioti

526 Vincenzo'' for the kind cooperation.
