Abstract

Traditional Mozzarella is a fresh cheese produced in Italian local market without additives that shows a short shelf life of about 5 days. This work tested the use of natural additives (bergamot juice concentrate-BJ and calcium lactate-CL) in preserving liquid for a Mozzarella cheese with the aim to extend its shelf life, regarding the microbial growth and the overall cheese quality. Results of qualitative analyses showed that the preserving liquid with the mix of BJ and CL promoted an extension of mozzarella shelf life up to 20 days. A reduced growth of Pseudomonas species was evidenced after 5 days of storage, whereas no inhibition of lactic acid bacteria was observed for the storage period. Moreover, mozzarella cheese packed in mixed preserving liquid possessed better textural properties, evidenced by the lowest proteolysis index measured after 13 days of storage, and a good antioxidant activity.

Introduction

Mozzarella cheese is an Italian unripened cheese with a milky fresh taste and higher moisture content (60-65%) than in other dairy products, obtained by lactic acid bacteria fermentation (lactofermented mozzarella) or by direct injection of organic acids into the milk (acidified mozzarella). It is packed until consumption immersed into a preserving liquid, constituted by water, and sometimes NaCl or organic acids (Mucchetti & Neviani, 2006). Mozzarella cheese is easily perishable due to excessive microbial growth and also due to mass transfer (i.e. migration of salt and water) between the product and the preserving liquid: shelf life commonly ranges from 5 to 10 days, depending on the moisture level, microbial growth, manufacturing procedures and storage conditions (Faccia et al., 2019). In particular, the shelf-life of mozzarella cheese with high water content is 5 days (Altieri et al. 2005). Local firms are very interested to prolong its shelf life, with the aim to expand the business in larger national and international markets. Among the different possibilities for dairy products, as new packaging solutions (Piscopo et al., 2015), greater processing sustainability (Piscopo et al., 2019) and reduction of wastes and food losses (Falcone et al., 2017), alternative compositions of preserving liquids can be considered, in particular for the direct interaction with the cheese for microbiological, sensorial and chemical quality. Different studies evaluated NaCl in the preserving liquid for mozzarella cheese: it can preserve its texture delaying the water diffusion between mozzarella cheese and brine; it improved its shelf life by control of undesirable microbial growth; it affected positively water activity and enzyme activity of cheese (Guinee & Fox, 2004). The substitution of Na cation with others as Ca, Mg, NH_4 was considered an alternative to sodium in cheese to reduce the possible healthy damage (Ayyash et al.2013) and to promote protein to protein interactions within the cheese matrix (Faccia et al., 2013). Before, this salt was added during cheesemaking process: it was found that it improves gel strength and the release of water from the matrix as reported by Pastorino et al. (2003). In some works, were reported that addition of calcium chloride to governing liquid of mozzarella improved both the structure and taste (Faccia et al., 2011) and could have a certain bacteriostatic effect on Pseudomonas spp (Faccia et al., 2013). The addition of CaCl to governing liquid improved organoleptic parameters and showed a certain bacteriostatic effect on Pseudomonas spp (Faccia et al., 2009, 2011, 2013).

Plant extracts, essential oils, juices and other derivatives can be used as alternative agents in the food preservation for their important compounds which could reduce microbial count (Romeo et al., 2008) and improve the quality of food products (Romeo et al., 2010). Citrus fruits, commonly widespread and consumed in South of Italy are important source of several biomolecules with functional and antioxidant properties (Sicari et al., 2016). Bergamot (Citrus Bergamia Risso) is a natural hybrid fruit derived from bitter orange and lemon, come from the Province of Reggio Calabria, and used mostly for the extraction of essential oil and in less extent for juice (Scerra et al., 2018). In the last period, Bergamot fruits are associated with benefic effects for human healthy for their anticancer, antimicrobial, antioxidant, anti-infiammatory activities (Celia et al., 2013). Bergamot derivatives possesses a high quantity of bioactive of components (phenolics, flavonoids and other antioxidant compounds (Russo et al., 2016; Giuffrè et al., 2019) which throw light on the possible use in food processing to improve the functional and microbiological characteristics. Moreover, it was demonstrated by literature that essential oil and juice of bergamot (Fisher and Phillips, 2006; Pedonese et al., 2017; Rossi et al., 2018) reduced the pathogens microbial growth and limited the biofilm formation of bacteria strains and their motility.

Thus, in this research governing liquids containing bergamot concentrated juice and calcium lactate were evaluated for the preserving of lacto-fermented mozzarella cheese in relation to microbiological, sensorial and chemical characteristics.

Material and methods

Preparation of samples

A concentrated of Bergamot juice (BJC) was used in the preserving liquid for lacto-fermented mozzarella cheeses (125 g of weight, moisture >55%). BJC was collected in a factory, Delizie della Natura, located in Reggio Calabria (Italy), transported in containers certified microbiologically safe, and stored at 4° C in dark conditions for 24 h before their use and analysis. Calcium lactate (CL) was also used in the preserving liquid composition. Lacto-fermented mozzarella cheeses were manufactured. in a firm located in Reggio Calabria (Italy). Usually mozzarella cheeses are immersed in tap water, microbiological safe, and sold with a shelf life of 5 days. For the experimental plants three preserving liquids were evaluated on mozzarella cheeses shelf life and mozzarella cheeses samples were therefore named as follows: BJ-M (0,1 % BJ v/v); BJ+CL-M (0,05 % BJ v/v + 0,2 % CL w/v); Control (tap water) All samples were submitted to chemical, microbiological and sensory analyses, immediately after 1 day of manufacturing and after 5, 7, 13, and 20 days of storage at 4°C.

Microbiological analyses

The microbiological analyses were performed according to the IDF standard protocol (IDF, 2001). 10 g sample of lacto-fermented mozzarella cheese (mixed centre and edge portions) was aseptically taken and mixed with 90 mL sterile Ringer's solution and homogenised for 3 min in a stomacher bag filter by Bag Mixer (Interscience, Saint Nom, France). Subsequently, decimal dilutions of homogenates were made using the same diluent, and the dilutions were plated on appropriate media in Petri dishes. Bacterial counts were determined in duplicate. Total bacterial count (TBC) was assessed after incubation on Plant Count Agar 90 (PCA-Oxoid, Milan, Italy) at 26 °C for 48 h; total lactic acid bacteria (LAB) were enumerated after anaerobic incubation in MRS Agar (Oxoid, Milan, Italy) at 32°C for 48 h. Pseudomonas spp. count was assessed at 25 °C for 48 h in Pseudomonas Agar Base 93 (Biolife, Milan, Italy) added of CFC Pseudomonas supplement (Biolife, Milan, Italy). The results were expressed as Log_{10} cfu g^{-1}.

Titratable acidity, pH, aw and moisture

Titratable acidity and pH were evaluated on water extract obtained from homogenization of 10 g of mozzarella cheese. For the titratable acidity, expressed as lactic acid %, and pH measurement 10 mL of water extract was analyzed according to AOAC methods, (1980a; 1980b). The percentage of moisture was evaluated on 5 g of sample following the method AOAC, 1990. Water activity value was obtained by mean of LabMaster-aw instrument (Novasina, Lachen, 106 Switzerland).

Evaluation of proteolysis

The evolution of proteolysis of lacto-fermented mozzarella cheese samples after (1, 13 and 20 days of storage) was evaluated according to Zoidou et al. (2015). Total nitrogen (TN) was determined in 0.5 g of mozzarella cheese was analyzed by means of the Kjeldahl method with Foss equipment (Tecator™ and Kjeltec™ 8400 analyser unit, Fisher Scientific, Foss North America). For the determination of water-soluble nitrogen (SN) ten grams of cheese was homogenised in 100 g of distilled water by mean the Ultra-Turrax T 25 basic. After 60 min at 40 °C, the cheese dispersion was re-homogenised under the same conditions. The homogenate was centrifuged at 3000 rcf for 30 min at 6 °C, and the supernatant was filtered through filter paper (Whatman, 0,45 µm). The filtrate (10 mL), water-soluble extract of the cheese, was used for the determination of water-soluble nitrogen (SN) of cheese by means of the Kjeldahl method. Furthermore, 25 mL of the water-soluble extract were mixed with an equal quantity of TCA or trichloroacetic acid (24% w/w), remaining overnight at 4°C after which the mixture was filtered through filter paper. Fifteen grams of the supernatant were used for the determination of 12% TCA-soluble N of the cheese (TCASN), and analyses was carried out by means of the Kjeldahl method. The results were expressed as percentage values of primary proteolysis (WSN /TN) and secondary proteolysis (ratio of TCASN /TN).

Texture profile analysis

Texture profile analysis (TPA) of mozzarella cheese samples was performed by TA-XT Plus Texture Analyzer (Stable Micro Systems, Godalming, Surrey, UK) evaluating hardness, adhesiveness, cohesiveness, springiness, gumminess, chewiness and resilience. These parameters were evaluated after a compression test with two successive cycles performed on whole mozzarella (5 mm sec^{-1} of test speed, 18 mm of distance, 5 s of time, 5 g of force, P/100 aluminum compression probe with a 100 mm of diameter) and after an elaboration of results by mean the Texture Expert for Windows Stable Micro Systems.

Antioxidant properties of water-soluble extracts

In order to characterize and to evaluate the total antioxidant capacity of cheese samples two different and complementary assays were used. The samples were evaluated for their antiradical activity against 2,2’-azinobis-(3-ethylbenzothiazoline-6-sulfonic acid) (ABTS) and 2,2’-azobis (2-methylpropionamide) dihydrochloride (AAPH) radicals. All data were then expressed as Trolox Equivalents (µmol TE g^{-1}) by using a standard curve (0.25-2.0 µM Trolox, 6-hydroxy-2,5,7,8-tetramethychroman-2-carboxylic acid). Trolox equivalent antioxidant capacity (TEAC) was determined by the decolorization assay using ABTS+ radical cation according to the method of Re et al. (1999). ABTS solution (2900 µL) was reacted with 100 µL of methanol extract (10 g of mozzarella sample mixed to 50 mL of methanol:water, 80:20, v:v) and the absorbance (734 nm) was measured after 6 min in the dark in a UV-VIS spectrophotometer (Agilent, Santa Clara, California, USA). The ORAC assays was evaluated according to the method of Zulueta et al. (2009). The assay was carried out with 20 µL of methanol extract, 150 µL of fluorescein and, 25 µL of AAPH solution, at 37 °C at each minute of the total 60 min and ORAC values, were calculated from the differences of areas under the fluorescence decay curves between the blank and the samples.

Statistical analysis

All experimental data were processed using SPSS Statistics 15.0 software and were compared by statistical analysis of variance (one-way ANOVA and Multivariate analysis). Tukey’s multiple range test was used to determine significant differences among samples ($p < 0.05$). The analyses were performed in triplicate and the results were expressed as mean ± standard deviation.

Results and discussions

Microbiological analyses highlighted a microbial growth as expected during the 20 days. Pseudomonas spp. count greatly increased after 5 days with highest values for BJ-M and Control samples (4 Log_{10} CFU g^{-1}). BJ+CL-M presented a lower load that tended to slightly increase during the storage, reaching the counts of the other samples without further variation up to 20 days. These results demonstrated that concentrated bergamot juice and calcium lactate, when associated, can inhibit Pseudomonas species as show in Figure 1. After 13 days BJ-M possessed the lowest Pseudomonas count. For the characteristics of texture, only BJ+CL mozzarella cheeses kept to 20 days with a TBC of 6.5 Log_{10} CFU g^{-1}. BJ+CL-M sample showed the highest total bacterial count with high significant differences at 7 days (6.75±0.01 Log_{10} CFU g^{-1}, $p<0.01$) and 13 days (6.98±0.05 Log_{10} CFU g^{-1}, $p<0.01$). Probably, it is associated to the major content of lactic acid bacteria (at each monitoring time $p<0.01$) with the following values: 6.13±0.03 and 6.94±0.01 Log_{10} CFU g^{-1} at 7 and 13 days respectively, as explained in the graph of Figure 1 (a and b) as confirmed by Pearson’s correlation coefficient ($r = 0.960$, $p<0.05$). Time and preserving liquid have significantly influenced microbiological parameters (LAB and Pseudomonas spp.) by Multivariate analysis ($p<0.01$): preserving liquid composition did not affect the evolution of TBC in mozzarella cheese samples ($p>0.05$). Our results are in contrast with Ayyash & Shah, (2011) that reported a stronger effect of brine on LAB counts in mozzarella samples. TBC did not were instead affected by studied variables: preserving liquids and storage time ($p>0.05$).

Table 1 showed the results of acidity, pH, a_w and moisture of lacto-fermented mozzarella samples. There weren't significant differences among samples about titratable acidity, pH and a_w after 1 day. Values of titratable acidity weren't significantly different among samples at each monitored time except for the 13th day where significantly higher values ($p<0.05$) were found in the Control sample (0,19 % lactic acid). Moreover, results of water activity did not highlight significant differences related to preserving liquid composition and storage time. BJ-M showed generally the highest pH values during the monitoring days whereas lower pH was observed in BJ+CL-M probably for the larger acidification process due to the higher LAB count. This last assessment was also confirmed by correlation results of Pearson's coefficient ($r = -0.855$, $p<0.05$). Primary proteolysis in cheese may be defined as those changes in α-, β, χ-, caseins, peptides, and other minor bands. Secondary proteolysis products could include those peptides, small fragments of proteins and amino acids which are soluble in acid solutions (Rank *et al.*, 1985). The extent of primary and secondary proteolysis in the different samples and storage time are shown in figure 2: The primary proteolysis, expressed as WSN/TN, increased in all samples, with higher values for Control sample and lower values for BJ-M and BJ+CL-M samples. As observed by Thibaudeau et al. (2015) storage time significantly influenced the mozzarella cheese proteolysis ($p<0.01$ for primary proteolysis and $p<0.05$ in secondary proteolysis). Therefore, preserving liquid composition affected only the primary proteolysis ($p<0.05$) but not secondary proteolysis. So, the effect of bergamot with calcium lactate preserves the evolution of proteolysis with differences highly significant among sample as found by Anova one-way analysis ($p<0.01$).

Texture profile analysis (TPA) of all samples during the storage were shown in Table 2. Time and preserving liquid composition significantly affect TPA: in particular for hardness, gumminess and chewiness ($p<0.01$). At the initial time the Control had the higher hardness values (9271,54); then this parameter decreased in all samples for the exchange from paste to governing liquid and from governing liquid to paste of salts and water. After 13 days of storage BJ+CLM samples have shown the highest hardness (4309.27 g) with highly significant differences among samples ($p<0.01$). Use of calcium lactate as alternative to common used salts contributes to avoid the surface deterioration because of the presence of ionic calcium that counterbalances the sequestering action of the calcium bound to the casein network due to acidic action: preserving the integrity of the mozzarella surface is a primary aim, since it represents a barrier to the mass transfer (Faccia et al., 2019). Literature suggested that some texture parameters, like adhesiveness, were not useful for fresh cheese as mozzarella (Fiszman & Damàsio, 2000; Halmos et al. 2003): by multivariate analysis time didn't affect adhesiveness ($p>0.05$). TPA springiness and cohesiveness for all samples ranged from 0.85 to0.75 and 0.95 to -to 0.82 respectively. The chewiness is, defined as the energy required for disintegrating solid food and obtained by TPA hardness x TPA springiness x TPA cohesiveness: as cheese hardness value increases as also chewiness one increases (Bourne, 2002). The Control sample had showed higher values at initial time (6494,15) and the BJ+CL-M sample after 13 days (2822,88), contrarily to Fogaça et al. (2017) in a work about TPA parameters of mozzarella cheese.

Results of antioxidant activity of mozzarella cheese sample are given in Figure 3. Antioxidant activity of samples increased throughout the storage period with highly significant differences by Multivariate analysis ($p<0.01$). Also, preserving liquid composition influenced it at each storage time: in particular, highly significant differences were found among samples for TEAC ($p<0.01$) and for ORAC ($p<0.05$). TEAC evaluated for BJ+CL-M sample increased after 5 days preserving the greater antioxidant activity during all the storage time with a value of 3.83 ± 0.03 µM TE g^{-1} at 13 days and 6.17 ± 0.03 µM TE g^{-1} at 21 days (data not shown). Results of ORAC showed that the sample with bergamot concentrated juice had higher values since initial time and in particular after one week from production: at seven days BJ-M had value of 6.59 ± 0.28 µM TE g^{-1}. Literature showed that LAB are important for the development of the biochemical characteristics and the releasing of bioactive peptides, in particular during the first weeks in cheese (Santiago-López et al., 2018) and that the bioactivity of cheese is mainly developed during the storage time (Hossain et al., 2018): in fact a correlation between Lab and ORAC was found after five days ($r = 0.822$).

Conclusions

Lacto-fermented mozzarella cheeses stored in preserving liquid with bergamot juice concentrate and calcium lactate (BJ+CL-M) reached 20 days of shelf life, whereas those stored with bergamot juice concentrated and tap water (BJ-M, Control respectively) reached 13 days for the collapse of mozzarella structure visually observable and the worst microbiological quality. These results indicated a shelf-life extension compared to commonly 5 days for this cheese without chemical additives or stored in modified atmosphere or with active coating. Moreover, the 20 days of shelf life were achieved with the use of calcium lactate and a natural product that enhances the final product and the local market.
